Example: Pneumonia detection

Our model, CheXNet, is a 121-layer convolutional neural network that inputs a chest X-ray image and outputs the probability of pneumonia along with a heatmap localizing the areas of the image most indicative of pneumonia.

We train CheXNet on the recently released ChestX-ray14 dataset, which contains 112,120 frontal-view chest X-ray images individually labeled with up to 14 different thoracic diseases, including pneumonia. We use dense connections and batch normalization to make the optimization of such a deep network tractable.

Figure: Rajpurkar et al. (2017). Chexnet: Radiologist-level pneumonia detection on chest x-rays with deep learning. arXiv preprint arXiv:1711.05225.

Why Not Use FFNN for Images?

- **Parameter explosion:** A fully-connected layer ignores image structure.

$$256 \times 256 \times 3 \approx 200,000 \text{ inputs}$$

A single hidden layer with 1,000 units would require

$$200,000 \times 1,000 = 200 \text{ million parameters.}$$

Why Not Use FFNN for Images?

- **Parameter explosion:** A fully-connected layer ignores image structure.

$$256 \times 256 \times 3 \approx 200,000 \text{ inputs}$$

A single hidden layer with 1,000 units would require

$$200,000 \times 1,000 = 200 \text{ million parameters.}$$

- **Locality is ignored:** Nearby pixels are strongly correlated. FFNNs treat all pixels as independent inputs.
- **Missing invariances:** Images contain translation/shift invariance. MLPs must *learn* this from data instead of building it in.
- **What CNNs do intuitively:**
 - Look at small local regions (receptive fields)
 - Reuse the same filter across the image (weight sharing)
 - Build hierarchical features: edges → textures → shapes

 - Examples
- Transfer learning
- Practical Methodology

Convolution

- Different definitions are common, one example:

$$y(t) = \int x(\tau)k(t - \tau)d\tau = (x * k)(t)$$

- Intuition: "Weighting together two functions"
- In a convolutional layer:
 1. $x(t)$: Input
 2. $k(t)$: Kernel, filter, "feature"
 3. $y(t)$: Output, feature map

- Practical Methodology

Discrete Convolution

- If t is discrete (as in a grid):

$$y(t) = (x * k)(t) = \sum_{\tau=-\infty}^{\infty} x(\tau)k(t - \tau)$$

- In the case of images we have 2 discrete dimensions

$$Y(i, j) = (X * K)(i, j) = \sum_m \sum_n X(m, n)K(i - m, j - n)$$

- Practicalities

- Transfer learning
- Practical Methodology

Discrete Convolution

- If t is discrete (as in a grid):

$$y(t) = (x * k)(t) = \sum_{\tau=-\infty}^{\infty} x(\tau)k(t - \tau)$$

- In the case of images we have 2 discrete dimensions

$$Y(i, j) = (X * K)(i, j) = \sum_m \sum_n X(m, n)K(i - m, j - n)$$

- Sometimes the cross-correlation is called convolution:

$$Y(i, j) = (X * K)(i, j) = \sum_m \sum_n X(m, n)K(i + m, j + n)$$

1. $X(i, j)$: Input (2D)
2. $K(i, j)$: Kernel, filter, "feature" (2D)
3. $Y(i, j)$: Output, feature map (2D)

- Given an input image:

$$32 \times 32 \times 3$$

- Convolution layer parameters:

- Kernel size: 3×3
- Padding: $p = 1$
- Stride: $s = 1$
- Number of filters: $C_{\text{out}} = 16$

- Output height and width:

$$H' = \frac{32 - 3 + 2p}{s} + 1 = \frac{32 - 3 + 2}{1} + 1 = 32,$$

$$W' = \frac{32 - 3 + 2}{1} + 1 = 32.$$

- Final output tensor:

$$32 \times 32 \times 16.$$

Why Convolution Layers?

Why Convolution Layers?

- Captures local spatial structure
- Reduces the number of parameters (parameter sharing)
 1. The number and size of filters
 2. We use the same filters everywhere
- Example: a 1 megapixel, single channel, image (1000×1000 pixels)
 1. Dense network with 100 nodes: **100M** parameters
 2. CNN network with 100 3×3 filters: **1000** parameters (900 from filters, 100 bias terms)

Pooling Layers: Pros and Cons

- Pros

- Provides translation invariance
- Reduces spatial resolution → computational savings
- Helps prevent overfitting by reducing model capacity

- Cons

- Discards fine-grained spatial information
- Can hurt performance on tasks requiring precise localization (e.g., segmentation, object detection)
- Often replaced or reduced in modern architectures (e.g., strided convolutions)

See *Benefits of Max Pooling in Neural Networks: Theoretical and Experimental Evidence* by Matoba et al. (2023) for more details.

- Step 2: Freeze the convolutional base Train only the new classification head
- Step 3: Train the head first Use a higher learning rate (e.g., 10^{-3}).
- Step 4: Unfreeze top convolutional blocks Fine-tune with a *small* learning rate (e.g., 10^{-5}) to avoid destroying pretrained features.
- When it works best:
 - You have limited data
 - Your task is visually similar to pretrained data (e.g. ImageNet)
 - You want fast convergence and stable training
- When not to fine-tune: Extremely small datasets → risk of overfitting.

- Best performance: Larger model that is regularized well.
- Warning: Avoid **the algorithm rabbit hole**
- Adapt hyperparameters to get **optimal capacity**
- Hyperparameter Search Goal:
adjust the model capacity to match the complexity of the task.
- Marginal hyperparameter has a U-shaped error function (ideally)
- Neural Networks Steps:
 1. Get good training error. E.g. by tune learning rate and increasing capacity
 2. Tune hyperparameters (regularization):
Requires monitoring both training and test error

- Practicalities
- Introduction
- Computer Vision
- Convolution
- Convolutional Neural Networks
 - The Convolution Layer
 - The Pooling Layer
 - Regularization
 - Examples
- Transfer learning
- Practical Methodology

Hyper-parameter optimization

- Neural networks has many hyperparameters
- What is a hyperparameter in a neural network?

- Convolutional Neural Networks
 - The Convolution Layer
 - The Pooling Layer
 - Regularization
 - Examples
- Transfer learning
- Practical Methodology

Hyper-parameter optimization

- Neural networks has many hyperparameters
- What is a hyperparameter in a neural network?
- Grid search:
 - Setup a grid of potential values
 - For 1-4 hyperparameter: grid search can work well
 - Usually iterative/repeated grid search is best: start with three values, and work iteratively
 - Grows exponentially with the number of parameters

- Practicalities
- Introduction
- Computer Vision
- Convolution
- Convolutional Neural Networks
 - The Convolution Layer
 - The Pooling Layer
 - Regularization
 - Examples
- Transfer learning
- **Practical Methodology**

Hyper-parameter optimization

- Neural networks has many hyperparameters
- **What is a hyperparameter in a neural network?**
- Grid search:
 - Setup a grid of potential values
 - For 1-4 hyperparameter: grid search can work well
 - Usually iterative/repeated grid search is best: start with three values, and work iteratively
 - Grows exponentially with the number of parameters
- Random search
 - Specify a marginal distribution for each hyperparameter (additional work)
 - Common: uniform on log scale
 - Can also be done iteratively
 - Can be exponentially more efficient
 - Generally reduce the error faster in setting with many hyper parameters

Diagnosis and Debugging

- Practicalities
- Introduction
- Computer Vision
- Convolution
- Convolutional Neural Networks
 - The Convolution Layer
 - The Pooling Layer
 - Regularization
 - Examples
- Transfer learning
- Practical Methodology
- Visualize the model predictions
